Disclaimer

Quality Measures published by the American Academy of Neurology Institute and its affiliates are assessments of current scientific and clinical information provided as an educational service. The information: 1) should not be considered inclusive of all proper treatments, methods of care, or as a statement of the standard of care; 2) is not continually updated and may not reflect the most recent evidence (new evidence may emerge between the time information is developed and when it is published or read); 3) addresses only the question(s) or topic(s) specifically identified; 4) does not mandate any particular course of medical care; and 5) is not intended to substitute for the independent professional judgment of the treating provider, as the information does not account for individual variation among patients. In all cases, the selected course of action should be considered by the treating provider in the context of treating the individual patient. Use of the information is voluntary. AANI provides this information on an “as is” basis, and makes no warranty, expressed or implied, regarding the information. AANI specifically disclaims any warranties of merchantability or fitness for a particular use or purpose. AANI assumes no responsibility for any injury or damage to persons or property arising out of or related to any use of this information or for any errors or omissions.

**Importance and Prevalence of Mild Cognitive Impairment**

**Defining Mild Cognitive Impairment**

Mild Cognitive Impairment (MCI) is a syndrome rather than a disease. “MCI” is a term used to describe acquired objective cognitive deficits insufficiently severe to affect most usual daily activities. For purposes of this document the term “MCI” is used as a catchall phrase for diseases and disorders that cause acquired cognitive deficits not affecting a person’s usual activities. MCI does not necessarily represent a progressive dementia syndrome. Deficits have been observed or experienced for three months or more. MCI generally corresponds to the term “mild neurocognitive disorder” used in the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5).

**Prevalence and Impact of Mild Cognitive Impairment**

The prevalence of MCI increases as individuals age and is common in older populations. The AAN 2017 MCI guideline assessed the prevalence of MCI and cognitive impairment worldwide. MCI prevalence was 6.7% for those aged 60–64 years, 8.4% for those aged 65–69 years, 10.17% for those aged 70–74 years, 14.8% for those aged 75–79 years, 25.2% for those aged 80–84 years, and 37.6% for those aged 85 years and older.¹

Ton, et al. studied financial burden and healthcare utilization and found patients with aMCI found increasing financial burden due to lower annual household income and higher medical expenditures relative to those with normal cognition.² Zhu et al., estimated that annual direct medical costs for a person with MCI was $6,499 compared to $2,969 for those without MCI.³

**Measure Development Process**

The American Academy of Neurology Institute (AANI) charged this work group with developing new measures focused on improving outcomes for patients with MCI. The AANI identified non-voting facilitators from the Quality and Safety Subcommittee and Practice Committee to serve as methodological support and guide the work group to consensus decisions. A subject matter chair was identified. A call for work group volunteers was made through the AAN, the Alzheimer’s Association and professional organizations relevant to MCI. Work group members were selected based on review of disclosure statements, subject matter expertise, and measure development experience. The work group includes physician, advanced practice provider, advocacy, patient, and care partner representatives from professional associations and patient advocacy organizations to ensure measures developed included input from all members of the healthcare team and other relevant stakeholders. All work group members are required to disclose relationships with industry and other entities to avoid actual, potential, or perceived conflicts of interest. Disclosures are listed in Appendix A. Seated work group members were instructed to abstain from voting on individual measure concepts if a conflict was present.

The AANI measure development process involves a modified Delphi review by the work group to reach consensus on measures to be developed prior to a 21-day public comment and following public comment further refinement.⁴
Below is an illustration of the measure development process from proposals, discussion, research, evaluation, to approval.

A comprehensive search to identify published guidelines, measures, and consensus recommendations in the National Guidelines Clearinghouse, the National Quality Measures Clearinghouse, PubMed, MEDLINE, EMBASE, and the Cochrane Library occurred identifying 1,932 potential articles from 2013 to project launch in late 2017. The work group winnowed results to 227 articles of interest and of these seven guidelines and 32 systematic reviews or meta-analyses were identified.

The measures in this set are being made available without any prior testing. The AAN encourages testing of this measurement set for feasibility and reliability by organizations or individuals positioned to do so. Select measures will be beta tested once the set has been released. Testing is required prior to submission to CMS for consideration in Quality Payment Program’s (QPP) Merit-based Incentive Payment System (MIPS) and the National Quality Forum for possible endorsement. The measurement set will be reviewed for updates triennially.
2018 Mild Cognitive Impairment Measurement Set

The work group approved six measures listed in the table below. There is no requirement that all the measures in the measurement set be used. Clinicians and treatment teams are encouraged to identify the one or two measures that would be most meaningful to their patient populations and implement those measures to drive performance improvement in practice. Data should be collected for an initial benchmark period, and results used to drive meaningful changes to identify and improve performance and overall care provided to patients with MCI.

Other Potential Measures

The work group proposed 27 measure concepts addressing causation, cognitive and functional evaluation, diagnostic imaging and testing, disclosure of diagnosis, medications, neuropsychological testing, management, legal planning, care partner concerns, the role of exercise, enrollment in clinical trials, quality of life, and ongoing treatment and follow-up.

The AAN encourages work groups to focus development of measure concepts that are feasible, meaningful to quality improvement efforts, and address a known treatment gap. Ultimately the work group cannot develop all appropriate concepts due to resource limitations and efforts to reduce reporting burden for clinicians. The work group eliminated 8 proposed new concepts following a prioritization ranking. Those concepts were: clinical trial, exercise, legal planning, quality of life, and follow-up. The work group noted that there was opportunity to support use of existing measures already developed to address some of the proposed concepts rather than develop new measures specific to MCI. The work group recommends use of the following measures for this population to supplement the above MCI specific measures developed by the work group:

- CMS Advance care planning for patients 65 years and older
- AAN Advance care planning for patients 18 years and older with a primary neurologic disorder diagnosis
- CMS Maltreatment Screening
- AAN Axon Registry quality of life PROMIS measure

Following ranking, the work group bundled cognitive and functional assessment into one measure and bundled concepts into a causation or differential diagnosis measure. The work group rated measures on evidence, feasibility, and link to improved outcomes, and eliminated additional measures prior to discussion (See measure development graphic above). These concepts were:

- Counseling regarding supplements
- Counseling regarding acetylcholinesterase inhibitors and/or memantine
- Care planning visits

Although, the eliminated measures were not included in this measurement set, they are high-value concepts that will be retained for future measurement set updates as more evidence may support development or a treatment gap in care at that time.

Additional Measures for Patients with MCI

The AAN has developed additional measures that may be of interest to clinicians and teams treating patients with MCI. All AANI measures are available for free at: https://www.aan.com/policy-and-guidelines/quality/quality-measures2/quality-measures/
### 2018 MCI Measure Specifications

**Annual Cognitive Health Assessment for Patients 65 years and older**

<table>
<thead>
<tr>
<th>Measure Title</th>
<th>Annual Cognitive Health Assessment for Patients 65 years and Older</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Percentage of patients aged 65 and older who had cognition assessed.</td>
</tr>
<tr>
<td>Measurement Period</td>
<td>January 1, 20xx to December 31, 20xx</td>

<tr>
<td>Numerator</td>
<td>Patients who had cognition assessed* within the measurement period.</td>
</tr>
</tbody>
</table>

Patients who had cognition assessed* at least once during the measurement period.  
*Cognition assessed is defined as use of one of the following validated objective tools (Users are encouraged to review possible copyright and use requirements prior to administration, as well as, ability to have the informant(s) potentially complete the validated tool. The tools are not necessarily equal and interchangeable. Clinician judgment is needed in selecting and interpreting the appropriate tool.):

- Montreal Cognitive Assessment (MoCA)(1),
- Mini-Mental State Examination (MMSE)(1-2),
- Memory Impairment Screen (MIS)(1),
- Saint Louis University Mental Status examination (SLUMS)(3),
- Mini-Cog®(4),
- Clinical Dementia Rating (CDR)(5),
- Self-Administered Gerocognitive Examination (SAGE) (6), or
- Neuropsychological assessment results.

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded within the measurement period:

- “Order for referral for neuropsychological assessment”,
- “Neuropsychological results discussed/counseled/reviewed with patient”,
- “MoCA [OR SLUMS, MMSE, MIS, CDR, Mini-Cog, SAGE, or neuropsychological] results reviewed”, OR
- “MoCA [OR SLUMS, MMSE, MIS, CDR, SAGE, Mini-Cog] results” followed by numerical score
- Presence of CPT code on encounter date or within the measurement period for neuropsychological testing would meet the measure: 96116, 96136, 96138, 96146

| Required Exclusions | • Prior diagnosis of Mild Cognitive Impairment
• Prior diagnosis of dementia (See Appendix B for complete diagnostic codes) |
| Allowable Exclusions | • Patient declines cognitive health assessment on date of encounter
• On date of encounter, patient is not able to participate in a cognitive health assessment, including non-verbal patients, delirious, comatose, severely aphasic, severely developmentally delayed, severe visual or hearing impairment and for those patients, no knowledgeable informant available.
• Patient previously had a cognitive assessment in the measurement period and prior results noted. |
To perform well on this measure, we suggest using key phrases for collection in a registry. These key phrases should be recorded on the encounter date:

- “Patient unable to communicate, no informant present”
- “Patient unable to understand task”
- “Patient declines cognitive assessment tool”
- “Informant declines cognitive assessment”
- “Patient refuses cognitive assessment tool”
- “Informant refuses cognitive assessment”
- “Care partner [OR spouse, informant, caregiver] declines cognitive assessment”
- “Patient screened and results noted.”
- “Patient previously assessed for cognitive impairment and results present.”

<table>
<thead>
<tr>
<th>Allowable Exclusion Inclusion Logic</th>
<th>Allowable exclusions can only help measure performance. If a patient has an allowable exclusion but is found to meet the numerator that patient is included in the count to meet the measure.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exclusion Rationale</td>
<td>Patients with prior diagnoses of MCI and dementia are excluded from the measure to prevent duplicative measurement in the calendar year. These patients are subject to other screening and assessment measures. (See Harmonization with Existing Measures below.) Patients or informants need to be able and willing to complete assessment for the assessment results to be valid. Additionally, patients previously assessed in the measurement period may be excluded if prior results are noted to reduce duplicative assessments.</td>
</tr>
</tbody>

</tr>
<tr>
<td>Risk Adjustment</td>
<td>Not applicable for process measure.</td>
</tr>
<tr>
<td>For Process Measures Relationship to Desired Outcome</td>
<td>From AAN MCI Guideline: “Clinicians should assess for MCI with validated tools in appropriate scenarios (Level B). Clinicians should evaluate patients with MCI for modifiable risk factors, assess for functional impairment, and assess for and treat behavioral/neuropsychiatric symptoms (Level B).”(7)</td>
</tr>
</tbody>
</table>
The Alzheimer’s Association notes, “Informal observation alone by a physician is not sufficient (i.e., observation without a specific cognitive evaluation.”(8)

Opportunity to Improve Gap in Care

Opportunity exists to improve the recognition of MCI through routine screening of cognitive health in older adults who because of their age are at high risk. (8,9) The work group restricted the measure to patients over the age of 65, but encourages clinicians to screen all at-risk patients for MCI. The work group also notes an informant may help in identification of at-risk patients along with thorough cognitive assessment. Physicians fail to recognize about 50% of patients in their practice with significant cognitive deficits, missing an opportunity to offer appropriate evaluation and treatment. (10) Depending solely on a complaint is insufficient because patients may not recognize or report worsening memory problems to their physicians. (11) Although, there is conflicting evidence on the benefits of cognitive impairment screening for older adults, there is growing support for the assessment of patients over the age of 65 years old and the benefits of this screening. (12-13)

Harmonization with Existing Measures

Although numerous cognitive screening measures exist for disease-specific conditions (such as multiple sclerosis, Parkinson’s disease, dementia, and stroke), a cross-cutting measure is needed for all patients over the age of 65 years old for baseline assessment for MCI. Current measures focused on cognitive screening are listed below for clinician consideration when identifying the best measure to meet your population needs:

- Percentage of actively enrolled home-based primary care and palliative care patients who received an assessment of their cognitive ability.
- Percentage of patients, regardless of age, with a diagnosis of dementia for whom an assessment of cognition is performed and the results reviewed at least once within a 12-month period.

**Measure Title** | Cognitive and Functional Assessment for Patients with MCI and Memory Loss  
---|---  
**Description** | Percentage of patients with MCI or memory loss who received a cognitive and functional assessment.
  
**Measurement Period** | January 1, 20xx to December 31, 20xx

**Eligible Providers** | Medical Doctor (MD), Doctor of Osteopathy (DO), Neuropsychologist (PhD, PsyD), Psychologist (PhD, PsyD), Physician Assistant (PA), Advanced Practice Registered Nurse (APRN)

**Care Setting(s)** | Outpatient Care

**Ages** | Age 18 and older

**Event** | Office visit

**Diagnosis** | Memory Loss or Mild Cognitive Impairment (See code list below)

**Denominator** | Patients with diagnosis of memory loss or Mild Cognitive Impairment.

**Numerator** | A. Patients who had cognition assessed* at least once during the measurement period.  
* Cognition assessed is defined as use of one of the following validated objective tools (Users are encouraged to review possible copyright and use requirements prior to administration, as well as, ability have informant(s) potentially complete the screening tool. The tools are not necessarily equal and interchangeable. Clinician judgment is needed in selecting and interpreting the appropriate tool.):  
- Montreal Cognitive Assessment (MoCA)(1),  
- Mini-Mental State Examination (MMSE)(1-2),  
- Memory Impairment Screen (MIS)(1),  
- Saint Louis University Mental Status examination (SLUMS)(3),  
- Mini-Cog©(4),  
- Clinical Dementia Rating (CDR)(5), or  
- neuropsychological assessment results.

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded within the measurement period:  
- “Order for referral for neuropsychological assessment”*,  
- “Neuropsychological results discussed/counseled/reviewed with patient”,  
- “MoCA [OR SLUMS, MMSE, MIS, CDR, Mini-Cog, or neuropsychological] results reviewed”, OR  
- “MoCA [OR SLUMS, MMSE, MIS, CDR, Mini-Cog] results” followed by numerical score  
- Presence of CPT code on encounter date or within the measurement period for neuropsychological testing would meet the measure: 96116, 96136, 96138, 96146

B. Patients who had an assessment^ of functional status involving a knowledgeable informant at least once during the measurement period.  
^Assessment is defined as use of the  
- Lawton Instrumental Activities of Daily Living scale(6,7),  
- Barthel ADL Index(8),  
- Katz Index of Independence in Activities of Daily Living (9), or  
- Functional Activities Questionnaire (FAQ)(6,10),  
- Everyday Cognition (ECog)(11), or  
- Performance Assessment of Self-Care Skills (PASS) test (12).
To perform well on this measure, we suggest using key phrases for collection in a registry. These key phrases should be recorded on the encounter date, as IADL or ADL alone insufficient:

- “IADL or ADL” followed by (X out of 6)
- “ADL” followed by (“independent” OR “dependent”)
- “Lawton [OR Barthel, Katz, FAQ, ECog, PASS] results reviewed”, OR
- “Lawton [OR Barthel, Katz, FAQ, ECog, PASS] followed by numerical score”

C. Patients who had both a cognition and functional status assessment at least once during the measurement period.

<table>
<thead>
<tr>
<th>Required Exclusions</th>
<th>Allowable Exclusions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patients diagnosed with dementia (See Appendix B for complete diagnostic codes)</td>
<td>Patient unable to speak and no knowledgeable informant available to provide information.</td>
</tr>
</tbody>
</table>

For component A only:
- Patient declines to complete a cognitive health assessment tool.
- Patient previously had a cognition assessment in the measurement period and prior results noted.

For component B only:
- Knowledgeable informant declines to complete a functional status assessment.

To perform well on this measure, we suggest using key phrases for collection in a registry. These key phrases should be recorded on the encounter date:

- For both components
  - “Patient unable to communicate, no informant present”
  - “Patient unable to understand task”
- For Component A only
  - “Patient declines cognitive assessment tool”
  - “Care partner declines cognitive assessment tool”
  - “Patient refuses cognitive assessment tool”
  - “Care partner refuses cognitive assessment tool”
  - “Patient screened and results noted.”
  - “Patient previously assessed for cognitive impairment and results present.”
- For Component B only
  - “Informant declines functional status assessment”
  - “Care partner [OR spouse, informant, caregiver] declines functional status assessment”
  - “Informant refuses functional status assessment”
  - “Care partner [OR spouse, informant, caregiver] refuses functional status assessment”

**Opportunity to Improve Gap in Care**

Although we have focused our listings on cognitive screening measures, we do not wish to convey a sense of false equivalency between the various cognitive screens listed and more comprehensive neuropsychological assessment strategies. We acknowledge cognitive screening measurement strategies are limited by generally low sensitivity and specificity rates, whereas gold standard neuropsychological test batteries are more sensitive and specific.(14-16) For example, Chan, et al. have shown that 22% of acute stroke patients scored in the normal range on the MoCA, although 78% of these 'normal' patients were impaired on more comprehensive neuropsychological assessment.(17) Olson, et al. have also shown one-third of brain tumor patients diagnosed as cognitively impaired on comprehensive neuropsychological assessment obtained a perfect or near perfect MMSE score (29 or 30 out of 30). MoCA fared poorly as well.(18)

Cognitive screens, or combinations of rating scales and screens like that used in common MCI criteria,(19) leads to misdiagnosis in both directions - false positive and false negative errors - relative to gold standard neuropsychological testing. 'Misses' or false negative errors would be expected in a primary care setting with its reliance on very limited cognitive screening, and conventional MCI criteria leads to large false-positive (33%) as well as some false-negative (7%) errors.(20-22) The work group recommends referral to neuropsychology when indicated by the results of screening tests, and believes there are opportunities to improve direct comparisons of
sensitivity and specificity rates of various cognitive screens and some cognitive testing, both to one another as well as to gold standard neuropsychological assessment.

Marshall, et al. noted, “IADL impairment leads to early loss of independence and the ability to be an active member of society, while shifting many daily responsibilities to care partners and increasing their burden.”(23) By screening for IADL and ADL impairment on a routine basis, clinicians will be able to identify deficits and offer treatment solutions. It is anticipated that routine screening will improve rates of interventions. Further, Jefferson, et al. noted that assessing ADLS alone may not be sensitive to identify early functional changes related to MCI and additional cognitive impairment screening was indicated.(24) Ciro, et al. assessed performance of IADLs using the Performance Assessment of Self-Care Skills (PASS) test and showed that this more sensitive test could distinguish amnestic MCI patients from age-matched controls.(25) Although current performance rates for cognitive and functional impairment are not known, the work group believes there is opportunity for improvement.

### Harmonization with Existing Measures

No known similar measures for patients with MCI or memory loss.

#### Denominator
- Patients diagnosed with MCI

#### Numerator
- Patients informed of their MCI diagnosis, educated on cognitive prognosis, and counseled on treatment plan options at least once in the measurement period.

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded on the encounter date. To meet the measure all three components must be addressed:

- **Informed of MCI diagnosis**
  - “Patient informed of MCI diagnosis”
  - “Disclosed MCI diagnosis to patient”
  - “Diagnosis discussed”
  - “Dx discussed”

- **Educated on cognitive prognosis**
  - “Informed of cognitive prognosis”
  - “Educated on cognitive prognosis”
  - “Addressed prognosis concerns”

- **Counseled on treatment plan options**
  - “Developed treatment plan with patient”
  - “Discussed treatment plan options”
  - “Counseled on treatment plan options”

The following key phrases could be used to meet all three measure components via collection in a registry:

- “Diagnosis and treatment options discussed”
- “Dx and treatment options discussed”
- “Diagnosis and management discussed”
- “Dx and management discussed”
- “Diagnosis and education provided prior to treatment plan discussion”
- “Dx and education provided prior to treatment plan discussion”
- “Diagnosis and education provided before treatment plan developed”
- “Dx and education provided before treatment plan developed”

#### Required Exclusions
- None

#### Allowable Exclusions
- Patient declines information on their diagnosis.
- Patient declines education on cognitive prognosis.
- Patient declines counseling on treatment plan options.
- Patient is actively suicidal or expressing self-harm statements.
To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded on the encounter date:

- “Patient declines information on their diagnosis”
- “Patient declines education on cognitive prognosis”
- “Patient declines counseling on treatment plan options”
- “Patient refuses information on their diagnosis”
- “Patient refuses education on cognitive prognosis”
- “Patient refuses counseling on treatment plan options”
- “Patient is suicidal”
- “Patient threatened self-harm”

### Allowable Exclusion Logic

Allowable exclusions can only help measure performance. If a patient has an allowable exclusion but is found to meet the numerator that patient is included in the count to meet the measure.

### Exclusion Rationale

- Patient may decline information on their diagnosis, prognosis, or treatment plan options, and a clinician should not force this information if it is detrimental to patient care.
- An exclusion is needed, if a patient is actively expressing suicidal ideation or self-harm and further discussion of their diagnosis, prognosis, or treatment plan options could be a detriment to care.

### Measure Scoring

Percentage

### Interpretation of Score

Higher Score Indicates Better Quality

### Measure Type

Process

### Level of Measurement

Provider

### Risk Adjustment

Not applicable for process measure.

### For Process Measures Relationship to Desired Outcome

**Process**
- Diagnosis disclosed to patient
- Education provided on prognosis
- Counseled on treatment plan options

**Outcomes**
- Patients and carepartners engaged in treatment planning
- Patients and carepartners prepared for potential decline
- Patients receiving appropriate care and following treatment recommendations

Patients with mild cognitive impairment have an increased risk of developing dementia (1-3). Patients and care partners who are informed of their diagnosis and receive education and
counseling regarding prognosis and available treatment plans will be more likely to follow recommendations and plan for future changes and potential decline.

| Opportunity to Improve Gap in Care | From AAN MCI 2017 Guideline: “Clinicians should discuss diagnosis, prognosis, long-term planning, and the lack of effective medicine options (Level B)”(1). Approximately 30-40% of dementia patients live alone at the time of their diagnosis.(2) In addition, fewer than 50% of patients with Alzheimer’s Disease report being told their diagnosis, and only slightly over 50% of care partners.(4) Knowing one’s diagnosis early is important for patients’ safety and future planning, tracking and follow up, and to help identify candidates for clinical trials.(4-6) A formal diagnosis also validates patient concerns that their cognitive impairment is not normal for their age. Clinicians interested in additional guidance on counseling elements and best practices are encouraged to review Grill, et al and Nuffield Council on Bioethics references. (5, 7) Work group recommends discussion occurs yearly to reflect changes in diagnosis, prognosis, and treatment planning options that may occur over the course of time. |
| Harmonization with Existing Measures | The AAN has developed a measure addressing disclosure of diagnosis for patients diagnosed with dementia. Available at: https://www.aan.com/policy-and-guidelines/quality-quality-measures2/quality-measures/geriatric-neurology/ A separate measure is needed for patients diagnosed with mild cognitive impairment. There is substantial variation in the denominator warranting a separate measure. |

| **Numerator** | Patients who have had treatment for contributing behavioral and psychiatric symptoms, hearing and vision deficits, sleep disturbances, neurologic diseases, OR medical illnesses following a comprehensive neuropsychological assessment * to determine potential contributing factors. |

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded on the encounter date:

- “Patient does not have any contributing behavioral health [OR hearing and vision deficits, sleep disturbances, neurologic diseases, OR medical illnesses] factor identified.”
- “Patient was treated for behavioral and psychiatric symptoms [OR hearing and vision deficits, sleep disturbances, neurologic diseases, OR medical illnesses].”
- “Patient is receiving treatment for behavioral and psychiatric symptoms [OR hearing and vision deficits, sleep disturbances, neurologic diseases, OR medical illnesses].”
- “Patient was referred to a specialist for further treatment.” (For example, psychiatry, psychology, ENT, sleep specialist, Occupational Therapy, Physical Therapy)

*The work group declined to delineate the required components of a comprehensive cognitive evaluation to determine cause due to concerns such a definition would require burdensome documentation changes by clinicians and the need to individualize patient evaluations depending upon the clinical context. A comprehensive neuropsychological assessment is always warranted, given its demonstrated improvements in diagnostic accuracy, stability, and prediction of progression over cognitive screening measurement strategies (1-3), and clinicians are encouraged to perform or refer the appropriate testing necessary to identify putative causes of the diagnosis. A comprehensive set of examination procedures includes a detailed history, neurological examination, neuropsychological examination, laboratory testing, and brain imaging. As with the dementia syndrome, in an evaluation often multiple causes and contributing factors are identified that may account for the mild cognitive impairment syndrome. Cognitive domains of memory, language, visuospatial, attentional and executive functions should be assessed. Common causes of MCI include disorders that also cause dementia including Alzheimer’s disease pathology, frontotemporal degeneration, Lewy body disease (including Parkinson’s disease), cerebrovascular disease, traumatic brain injury, substance abuse and medications, HIV infection, medical conditions, depression, anxiety, hypothyroidism, B12 deficiency, and often multiple etiologies. The goal is to interpret and weigh all evidence to arrive at a confident understanding of causation that can guide treatment. Any single procedure is considered insufficient. In the course of the evaluation, contributing factors would be identified and treated.

### Process Measures Relationship to Desired Outcome

From AAN MCI Guideline: “For patients diagnosed with MCI, clinicians should perform a medical evaluation for MCI risk factors that are potentially modifiable.(Level B)”(4) The AAN guideline notes that some cases of MCI are associated with reversible causes such as sleep apnea, depression and other medical conditions.(4) Also, behavioral/psychiatric symptoms are common in MCI and may be associated with greater functional impairment.(4) Further the guideline recommends, “For patients diagnosed with MCI, clinicians should perform serial assessments over time to monitor for changes in cognitive status (Level B).”(4) It follows that after assessment of contributing factors treatment should be provided to address and reduces these concerns limiting impact on cognitive impairment symptoms. Additionally, AAN guidelines are available for the diagnosis of dementia provides guidance for cognitive evaluation.(5)

| Process | • Objective evaluation performed  
| Diagnosis confirmed  
| Contributing factors identified  
| Contributing factors treated |
| Outcomes | • Reduced diagnostic errors  
| Contributing factors addressed reducing likelihood of disease progression |
Opportunity to Improve Gap in Care

This measure was developed after extensive conversation on a proposal to develop a measure assessing comprehensive evaluation. Evaluation and diagnostic measures pose a challenge as they may require searching for the lack of something, such as lack of a diagnosis or missed opportunities. The work group noted extensive potential burdens on a clinician to generate data and lack of current EHR technology to readily pull evaluation data from a text note without changing physician documentation practices. The comprehensive cognitive evaluations required for MCI and for dementia are similar. Appropriate testing can include advanced brain imaging methods (such as FDG and amyloid PET, dopamine SPECT, quantitative brain MRI) and specialized CSF and genetic testing, depending upon the clinical context such as presenting symptom, onset, rapidity of clinical course, medical illnesses, family history, neuropsychological and neurological findings. As a result, the work group chose to focus on treatment of identified contributing factors. This measure assumes a comprehensive neuropsychological assessment has been completed, and the work group encourages all clinicians to fully assess causation and contributing factors that explain MCI symptoms. The work group notes that such cognitive evaluations with gold standard neuropsychological tests demonstrate comparable utility vis-à-vis other biomarker strategies. (2,6,7) The next update of the measurement set will revisit this concept of comprehensive cognitive evaluation for future development.

The estimates of patients who have reversible forms of mild cognitive impairment vary. (8-10) For patients with reversible comorbid conditions treatment should be provided.

Behavioral Health

Cognitive impairment is often a feature of severe and persistent mental illness. (9) Some causes of MCI such as depression may be reversible as a result it is important behavioral health disorders be treated. (4,8-10) Symptoms of depression can be seen early on among those who develop signs of MCI. (11,12) At autopsy, greater numbers of amyloid plaques and neurofibrillary tangles have been identified in the hippocampi of Alzheimer patients who have had a life-long history of depression, compared to non-depressed AD patients. (14)

Hearing and Vision Deficits

Hearing loss is common and can contribute to memory and cognitive complaints; it affects performance on cognitive assessment, and is potentially correctable, at least in part. (4,6) Hearing loss increases with age (15), and the American Speech-Language-Hearing Association recommends a hearing test every three years after the age of 50. (16) A meta-analysis by Wei et al. found that hearing impairment is associated with a higher risk of MCI and dementia among older adults. (17) Lin concluded that hearing loss is independently associated with accelerated cognitive decline. (18)

Visual loss is common in older people and may cause memory and cognitive complaints; it affects performance on cognitive assessment and is potentially correctable, at least in part. (4,6) Chen et al. found that vision impairment is associated with lower cognitive function. (19) The American Academy of Ophthalmology recommends comprehensive eye exam every one to three years for those aged 55 to 64, and every year or two after the age of 65. (20)

Sleep disorders

There is a link between sleep disturbances, such as insomnia, sleep disordered breathing, excessive daytime sleepiness, sleep-related movement disorder, circadian rhythm sleep disorder, and others, and an increased risk of dementia. (21,22) Sleep disturbances can cause memory disturbance and treating them may improve symptoms. (4,8,10)

Neurologic Diseases

Cognitive impairment is a sensitive indicator of brain dysfunction and occurs in many types of neurological diseases including vascular, autoimmune, traumatic, neurodegenerative, infectious
disorders and in the presence of seizures and space-occupying lesions. While these conditions often cause delirium or dementia, particularly early in the disease course or in more indolent conditions, mild cognitive impairment may occur. Some have received specific designations such as vascular cognitive impairment. (23) Multiple guidelines exist supporting the periodic assessment of cognition for specific neurologic diseases, such as multiple sclerosis (24,25), stroke (26), and Parkinson’s disease (27-30), indicating its prevalence and importance in these conditions.

**Medical Illnesses**

It would seem obvious that treatment should reflect cause and that modifiable factors should be identified and treated. (4,6-8) Several studies have pointed out the importance of treating hypertension, diabetes, obesity and hyperlipidemia in midlife as a way of preventing MCI and dementia in later life (31,32).

| **Numerator** | Patients who were taking anticholinergic medications* in the measurement period^.

^Measure performance is calculated on the date of the last encounter in the calendar year. This allows for clinicians and patients to adequately discuss and discontinue anticholinergic medications as clinically appropriate.

*Anticholinergic medications for this measure(1):

- Amitriptyline
- Amoxapine
- Atropine (excludes ophthalmic)
- Belladonna alkaloids
- Benzotropine
- Brompheniramine
- Carboxamine
- Carisoprodol
- Chlordiazepoxide
- Chlorpheniramine
- Chlorpromazine
- Chlorzoxazone
- Clemastine
- Clidinium-Chlordiazepoxide
- Clomipramine
- Clozapine
- Cyclobenzaprine
- Cyproheptadine
- Darifenacin
- Desipramine
- Dextromethorphan
- Dextroamphetamine
- Dicyclomine
- Dimenhydrinate
- Diphenhydramine (oral)
- Disopropamide
- Doxepine >6 mg/d
- Doxylamine
- Flavoxate
- Fesoterodine
- Homatropine (excludes ophthalmic)
- Hydroxyzine
- Hyoscymine
- Imipramine
- Loxapine
- Meclizine
- Metaxalone
- Methocarbamol
- Nortriptyline
- Olanzapine
- Orphenadrine
- Oxybutynin
- Paroxetine
- Perphenazine
- Prochlorperazine
- Promethazine
- Propantheline
- Protriptyline
- Scopolamine (excludes ophthalmic)
- Solifenacin
- Thoridazine
- Tolterodine
- Trifluoperazine
- Trihexyphenidyl
- Trimipramine
- Triprolidine
<table>
<thead>
<tr>
<th>Required Exclusions</th>
<th>• Patients without a diagnosis of MCI</th>
</tr>
</thead>
</table>
| Allowable Exclusions | • Patient at end-of-life or admitted to hospice care.  
|                      | • Patient receiving cancer chemotherapy.  
| To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded on the encounter date:  
|                      | • “Patient admitted to hospice care”  
|                      | • “Patient receiving hospice care”  
|                      | • “Patient receiving end-of-life …”  
|                      | • “Patient receiving cancer chemotherapy”  
|                      | • “Cancer chemotherapy continues”  
| Allowable Exclusion Inclusion Logic | Allowable exclusions can only help measure performance. If a patient has an allowable exclusion but is found to meet the numerator that patient is included in the count to meet the measure. |
| Exclusion Rationale | Patients who are at end-of-life or admitted to hospice care and those receiving cancer chemotherapy may require anticholinergic medications, and clinicians should have the option to excludes patients when clinically indicated in these situations. |
| Measure Scoring | Percentage |
| Interpretation of Score | Lower Score Indicates Better Quality |
| Measure Type | Intermediate Outcome |
| Level of Measurement | Provider |
| Risk Adjustment | Not applicable for this measure. |
| For Process Measures Relationship to Desired Outcome | “Use of anticholinergic medications remains a concern because it is associated with impaired cognitive and physical function and risk of dementia.”(1)  
Ruxton et al. systematic review found that drugs with anticholinergic effects may increase the risks of cognitive impairment, falls and all-cause mortality in older adults.(2) |

![Process

- Anticholinergic medications prescribed or taken over the counter
- Anticholinergic risks reviewed with patients and care partners

Intermediate Outcome

- Patients taking anticholinergic medications

Outcomes

- Reduction of inappropriate anticholinergic medications

Opportunity to Improve Gap in Care

The intent of this measure is to identify a baseline or benchmark performance rate for clinicians and over subsequent years reduce the number of patients taking anticholinergic medications. For this measure, a lower performance rate is indicative of higher quality. Zero performance rate is not the goal, as it will be impossible to completely discontinue all anticholinergic medications for patients with MCI.

This measure is specified for outpatient use, and it is not the intent to evaluate use of anticholinergic medication use in the short, inpatient care setting. The work group discussed possibility creating additional exclusions for all clinical scenarios were other anticholinergic medications are warranted, but declined to do so given the need for clinician discretion to meet the needs of individual patients. The work group started with the Beers criteria which demonstrates a strong link between anticholinergic medications and risk of development of cognitive impairment. As evidence evolves, the measure will be revisited and additional classes of medications such as benzodiazepines, antipsychotics, and opiates, may be added in future updates.

The work group expanded the list of eligible clinicians to include neuropsychologists and psychologists and note that these clinicians may not be prescribing medications. For all clinicians there is an education opportunity that arises at patient visits where anticholinergic medications are identified on the active medication list. Clinicians are encouraged to educate patients and their care partners on the risks of these medications.

It is important to take a careful medication history in patients with symptoms and signs of MCI, since many older adults may have memory problems that are due solely to anticholinergic drugs.(3,4) Gray and Hanlon report anticholinergics use is widespread for older adults.(5) In a six-year longitudinal study of 1,652 African American patients Campbell et al. found 53% of the population used a possible anticholinergic medication.(3)

When anticholinergic medications cannot be eliminated, a clinician should discuss the possibility of lowering medication dosage to reduce effects when anticholinergic medications to minimize potential adverse risks.(4)

Harmonization with Existing Measures

There are no known similar measures.

# Education Provided to Care Partners of Patients with MCI

<table>
<thead>
<tr>
<th>Measure Title</th>
<th>Education Provided to Care Partners of Patients with Mild Cognitive Impairment (MCI)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Percentage of patients with MCI whose care partner was educated on MCI diagnosis, cognitive prognosis, warning signs of disease progression to dementia, and treatment plan options at least once in the measurement period.</td>
</tr>
<tr>
<td><strong>Measurement Period</strong></td>
<td>January 1, 20xx to December 31, 20xx</td>
</tr>
<tr>
<td><strong>Eligible Population</strong></td>
<td>Eligible Providers: Medical Doctor (MD), Doctor of Osteopathy (DO), Neuropsychologist (PhD, PsyD), Psychologist (PhD, PsyD), Physician Assistant (PA), Advanced Practice Registered Nurse (APRN)</td>
</tr>
<tr>
<td><strong>Care Setting(s)</strong></td>
<td>Outpatient Care</td>
</tr>
<tr>
<td><strong>Ages</strong></td>
<td>Age 18 and older</td>
</tr>
<tr>
<td><strong>Event</strong></td>
<td>Office visit</td>
</tr>
<tr>
<td><strong>Diagnosis</strong></td>
<td>MCI</td>
</tr>
<tr>
<td><strong>Denominator</strong></td>
<td>Patients diagnosed with MCI</td>
</tr>
<tr>
<td><strong>Numerator</strong></td>
<td>Care partner(s) of patients with MCI who were provided* with education on 1. MCI diagnosis, 2. cognitive prognosis, 3. warning signs of disease progression to dementia, and 4. treatment plan options at least once in the measurement period</td>
</tr>
<tr>
<td>*Clinicians can meet numerator by referral to case manager, social work, nurse educator, health education counselor, care consultation by local, state, regional, or national organizations, or documentation of four key components.</td>
<td></td>
</tr>
</tbody>
</table>

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded within the measurement period, as education may not occur during the initial encounter and can occur throughout the measurement period:

- “Care partner [OR spouse, informant, caregiver] education provided”
- “Care partner [OR spouse, informant, caregiver] educated on diagnosis, prognosis, warning signs, and treatment plan options”
- “Referral to nurse educator [case manager, social work, health education counselor, or care consultation]”
- “Partner [OR spouse, informant, caregiver] education and referral provided.”

**Required Exclusions**

- Patients without a diagnosis of MCI

**Allowable Exclusions**

- Patient declines to identify a care partner
- Care partner cannot be identified
- Care partner declines any education

To perform well on this measure, the following key phrases are suggested for collection in a registry. These key phrases should be recorded on the encounter date:

- “Patient declines to identify…”
- “Patient refuses to identify…”
- “Unable to identify care partner [OR spouse, informant, caregiver]”
- “…declines MCI education”
- “…refuses MCI education”
- “…declines education on MCI”
- “…refuses education on MCI”

**Allowable Exclusion Inclusion Logic**

Allowable exclusions can only help measure performance. If a patient has an allowable exclusion but is found to meet the numerator that patient is included in the count to meet the measure.
<table>
<thead>
<tr>
<th>Exclusion Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Some patients refuse to identify a care partner, be unable to identify a care partner, or some care partners may refuse education. These patients should be excluded from the measure as clinicians are unable to meet measure intent and to force education may be detrimental in these situations.</td>
</tr>

<table>
<thead>
<tr>
<th>For Process Measures Relationship to Desired Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>For patients with MCI a knowledgeable informant is needed to determine whether there has been a change in cognitive status or function; patients may not adequately report deficits and function used to recognize MCI and change to dementia. (1-2) Grill, et al note the following: “Recommendation 2 – patients should have an informant present to assist in the diagnostic process. The preference of MCI patients who decline bringing an informant should be respected, but they should understand that this preference limits the information needed for the diagnostic process and patient care.” (3) Olazarán, et al., noted, &quot;Multicomponent interventions based on CG education and support delayed the institutionalization of ADRD persons with only modest amounts of resources used.&quot; (4) Ryan, et al. found care partner of individuals with MCI have a need for increased support services, particularly social areas at similar levels as those reported by care partners of patients with Alzheimer’s disease. (5) Savla J, et al. state: &quot;The results also highlight the importance of mild cognitive impairment-related education and support programs for care dyads to strengthen concordance, which is likely an important underpinning for effective coping as the illness progresses.&quot; (6)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Opportunity to Improve Gap in Care</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ryan, et al. found care partner of individuals with MCI have a need for increased support services, particularly social areas at similar levels as those reported by care partners of patients with Alzheimer’s disease. (5) Savla J, et al. state: &quot;The results also highlight the importance of mild cognitive impairment-related education and support programs for care dyads to strengthen concordance, which is likely an important underpinning for effective coping as the illness progresses.&quot; (6)</td>
</tr>
</tbody>
</table>
Education should be provided to care partners as soon as possible once diagnosis is confirmed. Clinicians will need to individualize this education to meet the patient and care partner needs and balance the timing of education upon individual patient and care partner characteristics. The work group encourages education be provided as soon as possible. The work group discussed excluding individuals without an identified care partner, and declined to develop this exclusion. Clinicians are encouraged to work with patients to review their social support network and develop care partners to address this concern.

The work group discussed adding additional components to this measure addressing assessment of care partner capacity and willingness to serve as well as education on hearing and vision co-morbidities. The work group declined to add these components at this time, however, clinicians are encouraged to address and document these concerns separate from the measure as needed to meet patient needs. Clinicians interested in additional guidance on counseling elements and best practices are encouraged to review Grill et al and Nuffield Counsel on Bioethics references. (7,8)

| Harmonization with Existing Measures | CMS and Mathematica have a draft measure, pending testing, assessing the identification of a care partner for patients diagnosed with dementia or MCI. As a result, the work group declined to create a duplicative measure assessing identification of a care partner and focused this measure on education of identified care partners. The CMS and Mathematica measure is currently pending testing. Once available to the public this measure will be posted on AAN.com. |
Flow Chart Diagram: Education Provided to Care Partners of Patients with MCI

1. **Was patient 18 years or older during the measurement period?**
   - **Yes** → **Patient INCLUDED in Eligible Population** → **During the measurement period, did patient refuse to identify a care partner?**
     - **No or N/A** → **On the date of the encounter, was the care partner not identified to receive education?**
       - **No or N/A** → **During the measurement period, did the identified care partner decline education?**
         - **No or N/A** → **Patient INCLUDED in Denominator**
         - **Yes** → **During the measurement period, was the identified care partner educated on MCI diagnosis, prognosis, warning signs of disease progression to dementia and treatment plan options at least once?**
           - **Yes** → **Patient met numerator criteria**
           - **No** → **Patient did NOT meet numerator criteria**
   - **No** → **Did the patient have at least one new or established patient visit with an eligible provider during the measurement period?**
     - **Yes** → **Patient NOT Included in Data Submission**
     - **No** → **Did patient have a diagnosis of MCI on any encounter during the measurement period?**
       - **Yes** → **Patient INCLUDED in Eligible Population** → **During the measurement period, was the identified care partner educated on MCI diagnosis, prognosis, warning signs of disease progression to dementia and treatment plan options at least once?**
         - **Yes** → **Patient met numerator criteria**
         - **No** → **Patient did NOT meet numerator criteria**
       - **No** → **Patient NOT Included in Data Submission**

## Appendix B: 2018 Dementia Diagnostic Codes

The term ‘dementia’ is used as an all-inclusive descriptor for the myriad diseases that can produce the syndrome. Please review individual measure specifications to identify whether the measure applies generally or has aspects that restrict its applicability to a particular disease or subset of diseases that produce dementia. In 2018, the AAN and American Psychiatric Association seated a small group of technical experts to refine ICD-10 codes used for the dementia management measurement set. The MCI measure development work adopted the below codes for dementia related measure exclusions.

<table>
<thead>
